00.tsfa.Intro Time Series	Factor Analysis (TSFA)
---------------------------	------------------------

Description

TSFA extends standard factor analysis (FA) to time series data. Rotations methods can be applied as in FA. A dynamic model of the factors is not assumed, but could be estimated separately using the extracted factors.

Details

Package: tsfa

Depends: R (>= 2.0.0), GPArotation, setRNG (>= 2004.4-1), tframe (>= 2006.1-1),

dse1 (>= 2006.1-1), dse2 (>= 2006.1-1)

Suggests: CDNmoney License: GPL Version 2.

URL: http://www.bank-banque-canada.ca/pgilbert

The main functions are:

loadings Extractloadings from an object estTSF.ML Estimate a time series factor model

factors Extract time series factors from an object

FAmodelFitStats Various fit statistics.

simulate Simulate a time series factor model summary Summary methods for \pkg{tsfa} objects tfplot Plot methods for \pkg{tsfa} objects TSFmodel Construct a time series factor model

An overview of how to use the package is available in the vignette tsfa (source, pdf).

FAfitStats 3

FAfitStats

Summary Statistics for a TSFA Models

Description

FAfitStats calculates various statistics for a TSFestModel or all possible (unrotated factanal) models for a data matrix. This function is also used by the summary method for a TSFestModel.

Usage

Arguments

object a time series matrix or TSFestModel.

diff. logical indicating if data should be differenced.

N sample size.

control a list of arguments passed to factanal.
... further arguments passed to other methods.

Details

In the case of the method for a TSFestModel the model parameters are extracted from the TSFestModel and the result is a vector of various fit statistics (see below). (Calculations are done by the internal function FAmodelFitStats.)

Most of these statistics are described in *Wansbeek and Meijer* (2000, WM below). The sample size N is used in the calculation of these statistics. The default is the number of number of observations, as in WM. That is, the number of rows in the data matrix, minus one if the data is differenced. Many authors use N-1, which would be N-2 if the data is differenced. The exact calculations can be determined by examining the code: print(tsfa:::FAmodelFitStats). The vector of statistics is:

chisq Chi-square statistic (see, for example, WM p298).

df degrees of freedom, which takes the rotational freedom into account (WM p169).

pval p-value

delta delta

RMSEA Root mean square error of approximation (WM p309).

RNI Relative noncentrality index (WM p307).

CFI Comparative fit index (WM p307).

MCI McDonald's centrality index.

GFI Goodness of fit index (Jöreskog and Sörbom, 1981, 1986, WM p305).

4 FAfitStats

AGFI Adjusted GFI (Jöreskog and Sörbom, 1981, 1986).

AIC Akaike's information criterion (WM p309).

CAIC Consistent AIC(WM p310).

SIC Schwarz's Bayesian information criterion.

CAK Cudeck & Browne's rescaled AIC.

CK Cudeck & Browne's cross-validation index.

The information criteria account for rotational freedom. Some of these goodness of fit statistics should be used with caution, because they are not yet based on sound statistical theory. Future versions of tsfa will probably provide improved versions of these goodness-of-fit statistics.

In the case of the default method, which expects a matrix of data with columns for each indicator series, models are calculated with factanal for factors up to the Ledermann bound. No rotation is needed, since rotation does not affect the fit statistics. Values for the saturated model are also appended to facilitate a sequential comparison.

The result for the default method is a list with elements

fitStats a matrix with rows as for a single model above, and a column for each possible number of factors.

seqfitStats a matrix with rows chisq, df, and pval, and columns indicating the comparative fit for an additional factor starting with the null (zero factor) model. (See also independence model, WM, p305)

The largest model can correspond to the saturated model, but will not if the Ledermann bound is not an integer, or even in the case of an integer bound but implicit contraints resulting in a Heywood case (see Dijkstra, 1992). In these situations it might make sense to remove the model corresponding to the largest integer, and make the last sequential comparison between the second to largest integer and the saturated solution. The code does not do this automatically.

Value

a vector or list of various fit statistics. See details.

FAmodelFitStats Calculate Summ

Calculate Summary Statistics with given FA Model Parameters

Description

Calculates various statistics with given Paramaters of an FA Model.

Usage

```
FAmodelFitStats(B, Phi, omega, S, N)
```

Arguments

```
B loadings.

Phi cov. matrix of factors.

omega vector of error variances

S sample covariance matrix.

N sample size.
```

6 LedermannBound

Details

This function is used by FAfitStats and would not normally be called by a user.

Value

a vector of various fit statistics.

LedermannBound

Ledermann Bound for Number of Indicators

Description

The Ledermann bound is given by the solution k for $(M-k)^2 \ge M+k$, where M is the number of indicator variables. The maximum possible number of factors is the largest integer smaller than or equal k.

Usage

LedermannBound(M)

Arguments

Μ

an integer indicating the number of indicator variables or a matrix of data, in which case ncol(M) is used as the number of indicator variables.

Value

The Ledermann bound, a positive real number.

FAfitStats

TSFmodel 7

TSFmodel	Construct a Time Series Factor Model
----------	--------------------------------------

Description

The default method constructs a TSFmodel. Other methods extract a TSFmodel from an object.

Usage

Arguments

obj The loadings matrix (B) in the default (constructor) method. In other methods,

an object from which the model should be extracted.

f matrix of factor series.

Omega Covariance of the idiosyncratic term.

Phi Covariance of the factors.

LB Factor score coefficient matrix.

positive.data

logical indicating if any resulting negative values should be set to zero.

names vector of strings indicating names to be given to output series.
... arguments passed to other methods or stored in the object.

Details

The default method is the constructor for TSFmodel objects. Other methods extract a TSFmodel object from other objects that contain one. The loadings and the factors must be supplied to the default method. Omega, Phi, and LB are included when the object comes from an estimation method, but are not necessary when the object is being specified in order to simulate. The model is defined by

$$y_t = Bf_t + \varepsilon_t,$$

where the factors f_t have covariance Φ and ε_t have covariance Ω . The loadings matrix B is $M \times k$, where M is the number of indicator variables (the number of series in y) and k is the number of factor series.

The estimation method estTSF.ML returns a TSFmodel as part of a TSFestModel that has additional information about the estimation.

Value

A TSFmodel.

Author(s)

Paul Gilbert

See Also

```
simulate.TSFmodel, simulate, estTSF.ML
```

Examples

checkResiduals.TSFestModel

Check Time Series Idiosyncratic Component

Description

The data is subtracted from the explained data (after differencing if diff is TRUE, the default) and the result is treated as a residual. Its covariance, the sum of the diagonal elements of the covariance, and the sum of the off-diagonal elements of the covariance are printed. The residual is then passed to the default method for checkResiduals which produces several diagonistic plots and (invisibly) returns statistics. See checkResiduals for more details. Calculation of partial autocorrelations can be problematic.

Some care should be taken interpreting the results. Factor estimation does not minimize residuals, it extracts common factors.

Usage

```
## S3 method for class 'TSFestModel':
checkResiduals(obj, diff.=TRUE, ...)
```

Arguments

obj	TSFestModel object for which the idiosyncratic component should be examined (as if it were a residual).
diff.	logical indicating if data and explained should be differenced.
	arguments to be passed to checkResiduals default methods.

estTSF.ML

Estimate Time Series Factor Model

Description

Estimate a TSFmodel.

Usage

Arguments

y a time series matrix.

p integer indication number of factors to estimate.

diff. logical indicating if model should be estimated with differenced data.

rotation character vector indicating the factor rotation method (see **GPArotation** for options).

12 estTSF.ML

methodArgs list passed to GPFoblq, and then to the rotation method, specifying arguments

for the rotation criteria. See GPFoblq.

normalize Passed to GPFoblq. TRUE means do Kaiser normalization before rotation and

then undo it after completing rotatation. FALSE means do no normalization.

See GPFoblq for other possibilities.

eps passed to GPFoblq
maxit passed to GPFoblq
Tmat passed to GPFoblq

BpermuteTarget

matrix of loadings. If supplied, this is used to permute the order of estimated factors and change signs in order to compare properly.

factorNames vector of strings indicating names to be given to factor series.

Details

The function estTSF.ML estimates parameters using standard (quasi) ML factor analysis (on the correlation matrix and then scaled back). The function factanal with no rotation is used to find the initial (orthogonal) solution. Rotation, if specified, is then done with GPFoblq. factanal always uses the correlation matrix, so standardizing does not affect the solution.

If diff. is TRUE (the default) the indicator data is differenced before it is passed to factanal. This is necessary if the data is not stationary. The resulting Bartlett factor score coefficient matrix (rotated) is applied to the undifferenced data. See *Gilbert and Meijer* (2005) for a discussion of this approach.

If rotation is "none" the result of the factanal estimation is not rotated. In this case, to avoid confusion with a rotated solution, the factor covariance matrix Phi is returned as NULL. Another possibility for its value would be the identity matrix, but this is not calculated so NULL avoids confusion.

The arguments rotation, methodArgs, normalize, eps, maxit, and Tmat are passed to GPFoblq.

The estimated loadings, Bartlett factor score coefficient matrix and predicted factor scores are put in a TSFmodel which is part of the returned object. The Bartlett factor score coefficient matrix can be calculated as

$$(B'\Omega^{-1}B)^{-1}B'\Omega^{-1}x$$

or equivalently as

$$(B'\Sigma^{-1}B)^{-1}B'\Sigma^{-1}x$$
,

The first is simpler because Ω is diagonal, but breaks down with a Heywood case, because Ω is then singular (one or more of its diagonal elements are zero). The second only requires nonsingularity of Σ . Typically, Σ is not singular even if Ω is singular. Σ is calculated from $B\Phi B' + \Omega$, where B, Φ , and Ω are the estimated values returned from factanal and rotated. The data covariance could also be used for Σ . (It returns the same result with this estimation method.)

The returned TSFestModel object is a list containing

model the estimated TSFmodel.

data the indicator data used in the estimation.

estimates a list of

estTSF.ML 13

estimation a character string indicating the name of the estimation function.

diff. the setting of the argument diff.

rotation the setting of the argument rotation.

uniquenesses the estimated uniquenesses.

BpermuteTarget the setting of the argument BpermuteTarget.

Value

A TSFestModel object which is a list containing TSFmodel, the data, and some information about the estimation.

factors, factorNames, TSFmodel,

predict

Predict Factor Scores from an Object.

Description

Predict factor scores using the predictor from object.

Usage

Arguments

object an object from which a matrix (predictor) can be extracted to apply to the data.

newdata data to which the predictor should be applied.

factorNames. names to be given to the calculated predicted factor score series.

Details

If newdata is not supplied then it is extacted from object if possible (which is normally the data the model was estimated with), and otherwise an error is indicated. The predicted factor scores are given by newdata %*% t(LB), where LB is the factor score coefficient matrix extracted from object. This is the Barlett factor score coefficient matrix if TSFmodel or TSFestModel objects were estimated with estTSF.ML.

Value

Predicted factor scores series.

simulate.TSFmodel 19

```
simulate.TSFmodel Simulate a Time Series Factor Model
```

Description

Simulate a TSFmodel to generate time series data (indicators) using factors and loadings from the model.

Usage

```
## S3 method for class 'TSFmodel':
simulate(model, Cov=model$Omega, sd=NULL,
    noise=NULL, rng=NULL, noise.model=NULL, ...)
## S3 method for class 'TSFestModel':
simulate(model, Cov=TSFmodel(model)$Omega, sd=NULL,
    noise=NULL, rng=NULL, noise.model=NULL, ...)
```

Arguments

Details

simulate. TSFmodel generates artifical data (indicators or measures) with a given TSFmodel (which has factors and loadings). The obj should be a TSFmodel. This might be a model constructed with TSFmodel or as returned by estTSF.ML.

The number of factor series is determined by the number of columns in the time series matrix f (the factors in the model object). This must also be the number of columns in the loadings matrix B (in the model object). The number of rows in the loadings matrix determines the number of indicator series generated (the number of columns in the matrix result). The number of rows in the time series factor matrix determines the number of periods in the indicator series generated (the number of rows in the matrix result).

simulate passes Cov, sd, noise, rng, and noise.model to makeTSnoise to generate the random idiosyncratic term ε_t , which will have the same dimension as the generated indicator series that are returned. ε_t will have random distribution determined by other arguments passed to makeTSnoise. Note that the covariance of the generated indicator series y_t is also influenced by the covariance of the factors f.

The calculation to give the generated artificial time series indicator data matrix y is

$$y_t = Bf_t + \varepsilon_t.$$

simulate. TSFmodel can use a TSFmodel that has only B and f specified, but in this case one of Cov, sd, noise, or noise. model must be specified as the default Omega from the model is not available.

Value

A time series matrix.

summary.TSFestModel
```

summary.TSFestModel Method for Base Generic

Description

Summary method for object in **tsfa**, such as the object returned by the estimation method estTSF.ML. See FAfitStats for details on the results from summary.TSFestModel.

Usage

```
## S3 method for class 'TSFmodel':
summary(object, ...)
## S3 method for class 'TSFestModel':
summary(object, ...)
## S3 method for class 'TSFmodelEstEval':
summary(object, ...)
## S3 method for class 'summary.TSFmodel':
print(x, ...)
## S3 method for class 'summary.TSFestModel':
print(x, ...)
## S3 method for class 'summary.TSFmodelEstEval':
print(x, digits = options()$digits, ...)
```

summaryStats 21

Arguments

```
object an object to summarize.

x an object to print.

digits precision of printed numbers.

... further arguments passed to other methods.
```

Value

a summary object.

summaryStats

Summary Statistics Calculations

Description

Calculates various statistics from a TSFmodelEstEval object returned by EstEval. This function is for use by the summary and tfplot methods and would not typically be called by a user.

Usage

```
summaryStats(object, ...)
## S3 method for class 'TSFmodelEstEval':
summaryStats(object, ...)
```

Arguments

```
object a TSFestModel object to summarize.
... further arguments passed to other methods.
```

Value

a list passed of statistics.

 ## S3 method for class 'factorsEstEval':
 diff(x, ...)
```

tframeMethods 23

Arguments

x an object.

x a TSFmodel, TSFestModel, TSFexplained, or TSFfactors object for plotting or

differencing.

diff. logical indicating if differenced data should be plotted.

percentChange.

logical indicating if percent change data should be plotted.

PCcentered. logical indicating if centered percent change data should be plotted.

summary. logical indicating if mean and 1 SD bounds should be plotted in place of all

estimates.

start See generic tfplot method
start See generic tfplot method
end See generic tfplot method
series See generic tfplot method

Title string to use for title of factors plot.

See generic tfplot method lty lwd See generic tfplot method See generic tfplot method pch See generic tfplot method col See generic tfplot method cex See generic tfplot method xlab ylab See generic tfplot method xlim See generic tfplot method See generic tfplot method ylim

graphs.per.page

See generic tfplot method

par See generic tfplot method
mar See generic tfplot method
reset.screen See generic tfplot method

. . . other objects to plot (currently unused).

Value

diff returns an object in which the time series data has been differenced. tfplot returns an invisible value but is executed mainly for the side-effect (plot).
